Lecture 16: Eigenvectors and Diagonalizability

March 8, 2024

Let $T : \mathbb{R}^3 \to \mathbb{R}^3$ be the linear transformation defined by $v \to Av$, where $A = \begin{bmatrix} -2 & 2 & 1 \\ 4 & 5 & -1 \\ -4 & -8 & 3 \end{bmatrix}$. The matrix of T with respect to the (ordered) basis B of $\mathbb{R}^3$ with elements $b_1 = \begin{bmatrix} 1 \\ 0 \\ 4 \end{bmatrix}$, $b_2 = \begin{bmatrix} 2 \\ -1 \\ 0 \end{bmatrix}$, $b_3 = \begin{bmatrix} 0 \\ -1 \\ 2 \end{bmatrix}$. is

$$\begin{bmatrix} 2 & 0 & 0 \\ 0 & -3 & 0 \\ 0 & 0 & 7 \end{bmatrix}.$$

This means: $T(b_1) = 2b_1$, $T(b_2) = 3b_2$, $T(b_3) = 7b_3$, and for any $v \in \mathbb{R}^3$,

$$\underbrace{[T(v)]_B}_{B-\text{coordinates of } T(v)} = \underbrace{A'[v]_B}_{\text{matrix}-\text{vector product}} .$$

Change of basis again

Let P be the matrix with the basis vectors from B as columns.

From Lecture 14, P^{-1} is the change of basis matrix from the standard basis to B. For any element v of $\mathbb{R}^3$, its B-coordinates are given by the matrix-vector product

$$[v]_B = P^{-1}v.$$

Equivalently, if we start with the B-coordinates, then the standard coordinates of v are given by

$$v = P[v]_B.$$

So P itself is the change of basis matrix from B to the standard basis.

Similarity - the relation of A and A'

Starting with A, the matrix of $T : \mathbb{R}^3 \to \mathbb{R}^3$ with respect to the standard basis, how do we find A' the matrix of T with respect to B?

1. Take a vector v of $\mathbb{R}^3$, written in B-coordinates as the column $[v]_B$.
2. Convert to standard coordinates (so that we can apply T by multiplying by A): take the product $P[v]_B$.
3. Apply T: left-multiply by A to get $AP[v]_B$. This column has the standard coordinates of $T(v)$.
4. Convert to B-coordinates: left-multiply by P^{-1}, the change of basis matrix from standard to B. This gives $P^{-1}AP[v]_B$. This column has the B-coordinates of $T(v)$.
5. Conclusion: For any element v of $\mathbb{R}^3$, the B-coordinates of $T(v)$ are given by $(P^{-1}AP)[v]_B$.

The B-matrix of T is $P^{-1}AP$, where P has the elements of B as columns.

Similar Matrices

Definition Two square matrices A and B are similar if $B = P^{-1}AP$ for an invertible matrix P.

Notes

1. Two distinct matrices are similar if and only if they represent the same linear transformation, with respect to different bases.
2. We can't tell by glancing at a pair of square matrices if they are similar or not, but there is one feature that is easy to check. The trace of a square matrix is the sum of the entries on the main diagonal, from top left to bottom right. If two matrices are similar, they have the same trace.
3. Similar matrices also have some other features in common, such as having the same determinant.
4. Our example showed that the 3×3 matrix $A = \begin{bmatrix} -2 & 2 & 1 \\ 4 & 5 & -1 \\ -4 & -8 & 3 \end{bmatrix}$ is similar to the diagonal matrix $\mathrm{diag}(2, -3, 7)$. We say A is diagonalizable in this situation.

Two equivalent interpretations of diagonalizability

1. From the diagonal form of A' we have $T(b_1) = 2b_1,\ T(b_2) = -3b_2$ and $T(b_3) = 7b_3$. This means that each of the basis elements b_1, b_2, b_3 is mapped by T to a scalar multiple of itself - each of them is an *eigenvector* of T.
2. We can rearrange the version $P^{-1}AP = A'$ to $AP = PA'$. Bearing in mind that $P = \begin{bmatrix} | & | & | \\ b_1 & b_2 & b_3 \\ | & | & | \end{bmatrix}$ and that $A' = \text{diag}(2, -3, 7)$, this is saying that

$$A\begin{bmatrix} | & | & | \\ b_1 & b_2 & b_3 \\ | & | & | \end{bmatrix} = \begin{bmatrix} | & | & | \\ b_1 & b_2 & b_3 \\ | & | & | \end{bmatrix}\begin{bmatrix} 2 & 0 & 0 \\ 0 & -3 & 0 \\ 0 & 0 & 7 \end{bmatrix} \Longrightarrow \begin{bmatrix} | & | & | \\ Ab_1 & Ab_2 & Ab_3 \\ | & | & | \end{bmatrix} = \begin{bmatrix} | & | & | \\ 2b_1 & -3b_2 & 7b_3 \\ | & | & | \end{bmatrix}$$

   This means that $Ab_1 = 2b_1$, $Ab_2 = -3b_2$ and $Ab_3 = 7b_3$, so that $B = \{b_1, b_2, b_3\}$ is a basis of $\mathbb{R}^3$ consisting of *eigenvectors* of A.

Eigenvectors and Diagonalizability

Definition An eigenvector of a square matrix A is a non-zero column vector v for which $Av = \lambda v$ for some scalar λ, called the eigenvalue of A to which v corresponds.

The eignvalues of A are the roots of its characteristic polynomial $\det(\lambda I_n - A)$.

The eigenspace corresponding to a particular eigenvalue λ is the set of all vectors v satsfying $Av = \lambda v$. It is a subpsace of the relevant $\mathbb{R}^n$, of dimension at least 1.

The matrix $A \in M_n(\mathbb{R})$ is diagonalizable if and only if $\mathbb{R}^n$ has a basis consisting of eigenvectors of A. In this case $P^{-1}AP$ is diagonal, where P is a matrix whose n columns are linearly independent eigenvectors of A. The diagonal entries of $P^{-1}AP$ are the corresponding eigenvalues.

Non-diagonalizabilty (two examples)

For $A \in M_n(\mathbb{R})$, it does not always happen that $\mathbb{R}^n$ has a basis consisting of eigenvectors of A.

Examples

1. The matrix $A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$ is diagonalizable in $M_2(\mathbb{C})$ but not in $M_2(\mathbb{R})$.
   This matrix represents a clockwise rotation through 90° about the origin. It does not fix any line in $\mathbb{R}^2$. Its characteristic polynomial is $\lambda^2 + 1$.
2. The matrix $B = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$ is not diagonalizable even over $\mathbb{C}$.
   This matrix represents a horizontal shear. Its characteristic polynomial is $(\lambda - 1)^2$ but its 1-eigenspace consists only of the X-axis. It does not have two linearly independent eigenvectors.
